## Lecture 20: Work, Average Value, Probability

### Application of Integration to Average Value

You already know how to take the average of a set of discrete numbers:

$$\frac{a_1 + a_2}{2} \text{ or } \frac{a_1 + a_2 + a_3}{3}$$

Now, we want to find the average of a continuum.

Figure 1: Discrete approximation to  $y = f(x)$  on  $a \leq x \leq b$ .

$$\text{Average} \approx \frac{y_1 + y_2 + \dots + y_n}{n}$$

where

$$a = x_0 < x_1 < \dots < x_n = b$$

$$y_0 = f(x_0), y_1 = f(x_1), \dots, y_n = f(x_n)$$

and

$$n(\Delta x) = b - a \quad \Longleftrightarrow \quad \Delta x = \frac{b - a}{n}$$

and

The limit of the Riemann Sums is

$$\lim_{n \rightarrow \infty} (y_1 + \dots + y_n) \frac{b - a}{n} = \int_a^b f(x) dx$$

Divide by  $b - a$  to get the continuous average

$$\lim_{n \rightarrow \infty} \frac{y_1 + \dots + y_n}{n} = \frac{1}{b - a} \int_a^b f(x) dx$$

Figure 2: Average height of the semicircle.

**Example 1.** Find the average of  $y = \sqrt{1-x^2}$  on the interval  $-1 \leq x \leq 1$ . (See Figure 2)

$$\text{Average height} = \frac{1}{2} \int_{-1}^1 \sqrt{1-x^2} dx = \frac{1}{2} \left( \frac{\pi}{2} \right) = \frac{\pi}{4}$$

**Example 2.** The average of a constant is the same constant

$$\frac{1}{b-a} \int_a^b 53 dx = 53$$

**Example 3.** Find the average height  $y$  on a semicircle, with respect to *arclength*. (Use  $d\theta$  not  $dx$ . See Figure 3)

Figure 3: Different weighted averages.

---

$$\text{Average} = \frac{1}{\pi} \int_0^\pi \sin \theta \, d\theta = \frac{1}{\pi} (-\cos \theta) \Big|_0^\pi = \frac{1}{\pi} (-\cos \pi - (-\cos 0)) = \frac{2}{\pi}$$

**Example 4.** Find the average temperature of water in the witches cauldron from last lecture. (See Figure 4).

Figure 4:  $y = x^2$ , rotated about the  $y$ -axis.

First, recall how to find the volume of the solid of revolution by disks.

$$V = \int_0^1 (\pi x^2) \, dy = \int_0^1 \pi y \, dy = \frac{\pi y^2}{2} \Big|_0^1 = \frac{\pi}{2}$$

Recall that  $T(y) = 100 - 30y$  and  $(T(0) = 100^\circ; T(1) = 70^\circ)$ . The average temperature per unit volume is computed by giving an importance or “weighting”  $w(y) = \pi y$  to the disk at height  $y$ .

$$\frac{\int_0^1 T(y)w(y) \, dy}{\int_0^1 w(y) \, dy}$$

The numerator is

$$\int_0^1 T \pi y \, dy = \pi \int_0^1 (100 - 30y)y \, dy = \pi(50y^2 - 10y^3) \Big|_0^1 = 40\pi$$

Thus the average temperature is:

$$\frac{40\pi}{\pi/2} = 80^\circ C$$

Compare this with the average taken with respect to height  $y$ :

$$\frac{1}{1} \int_0^1 T \, dy = \int_0^1 (100 - 30y) \, dy = (100y - 15y^2) \Big|_0^1 = 85^\circ C$$

$T$  is linear. Largest  $T = 100^\circ C$ , smallest  $T = 70^\circ C$ , and the average of the two is

$$\frac{70 + 100}{2} = 85$$

---

The answer  $85^\circ$  is consistent with the ordinary average. The weighted average (integration with respect to  $\pi y dy$ ) is lower ( $80^\circ$ ) because there is more water at cooler temperatures in the upper parts of the cauldron.

## Dart board, revisited

Last time, we said that the accuracy of your aim at a dart board follows a “normal distribution”:

$$ce^{-r^2}$$

Now, let’s pretend someone – say, your little brother – foolishly decides to stand close to the dart board. What is the chance that he’ll get hit by a stray dart?

Figure 5: Shaded section is  $2r_1 < r < 3r_1$  between 3 and 5 o’clock.

To make our calculations easier, let’s approximate your brother as a sector (the shaded region in Fig. 5). Your brother doesn’t quite stand in front of the dart board. Let us say he stands at a distance  $r$  from the center where  $2r_1 < r < 3r_1$  and  $r_1$  is the radius of the dart board. Note that your brother doesn’t surround the dart board. Let us say he covers the region between 3 o’clock and 5 o’clock, or  $\frac{1}{6}$  of a ring.

Remember that

$\text{probability} = \frac{\text{part}}{\text{whole}}$
---

Figure 6: Integrating over rings.

The ring has weight  $(ce^{-r^2})(2\pi r)(dr)$  (see Figure 6). The probability of a dart hitting your brother is:

$$\frac{\frac{1}{6} \int_{2r_1}^{3r_1} ce^{-r^2} 2\pi r dr}{\int_0^\infty ce^{-r^2} 2\pi r dr}$$

Recall that  $\frac{1}{6} = \frac{5-3}{12}$  is our approximation to the portion of the circumference where the little brother stands. (Note:  $e^{-r^2} = e^{(-r^2)}$  not  $(e^{-r})^2$  )

$$\int_a^b re^{-r^2} dr = -\frac{1}{2}e^{-r^2} \Big|_a^b = -\frac{1}{2}e^{-b^2} + \frac{1}{2}e^{-a^2} \quad \left( \frac{d}{dr}e^{-r^2} = -2re^{-r^2} \right)$$

Denominator:

$$\int_0^\infty e^{-r^2} r dr = -\frac{1}{2}e^{-r^2} \Big|_0^{R \rightarrow \infty} = -\frac{1}{2}e^{-R^2} + \frac{1}{2}e^{-0^2} = \frac{1}{2}$$

(Note that  $e^{-R^2} \rightarrow 0$  as  $R \rightarrow \infty$ .)

Figure 7: Normal Distribution.

$$\text{Probability} = \frac{\frac{1}{6} \int_{2r_1}^{3r_1} ce^{-r^2} 2\pi r dr}{\int_0^\infty ce^{-r^2} 2\pi r dr} = \frac{\frac{1}{6} \int_{2r_1}^{3r_1} e^{-r^2} r dr}{\int_0^\infty e^{-r^2} r dr} = \frac{1}{3} \int_{2r_1}^{3r_1} e^{-r^2} r dr = \frac{-e^{-r^2}}{6} \Big|_{2r_1}^{3r_1}$$

---

$$\text{Probability} = \frac{-e^{-9r_1^2} + e^{-4r_1^2}}{6}$$

Let's assume that the person throwing the darts hits the dartboard  $0 \leq r \leq r_1$  about half the time. (Based on personal experience with 7-year-olds, this is realistic.)

$$P(0 \leq r \leq r_1) = \frac{1}{2} = \int_0^{r_1} 2e^{-r^2} r dr = -e^{-r_1^2} + 1 \implies e^{-r_1^2} = \frac{1}{2}$$

$$e^{-r_1^2} = \frac{1}{2}$$

$$e^{-9r_1^2} = \left(e^{-r_1^2}\right)^9 = \left(\frac{1}{2}\right)^9 \approx 0$$

$$e^{-4r_1^2} = \left(e^{-r_1^2}\right)^4 = \left(\frac{1}{2}\right)^4 = \frac{1}{16}$$

So, the probability that a stray dart will strike your little brother is

$$\left(\frac{1}{16}\right) \left(\frac{1}{6}\right) \approx \frac{1}{100}$$

In other words, there's about a 1% chance he'll get hit with each dart thrown.

---

## Volume by Slices: An Important Example

Compute  $Q = \int_{-\infty}^{\infty} e^{-x^2} dx$

Figure 8:  $Q = \text{Area under curve } e^{(-x^2)}$ .

This is one of the most important integrals in all of calculus. It is especially important in probability and statistics. It's an improper integral, but don't let those  $\infty$ 's scare you. In this integral, they're actually easier to work with than finite numbers would be.

To find  $Q$ , we will first find a volume of revolution, namely,

$$V = \text{volume under } e^{-r^2} \quad (r = \sqrt{x^2 + y^2})$$

We find this volume by the method of shells, which leads to the same integral as in the last problem. The shell or cylinder under  $e^{-r^2}$  at radius  $r$  has circumference  $2\pi r$ , thickness  $dr$ ; (see Figure 9). Therefore  $dV = e^{-r^2} 2\pi r dr$ . In the range  $0 \leq r \leq R$ ,

$$\int_0^R e^{-r^2} 2\pi r dr = -\pi e^{-r^2} \Big|_0^R = -\pi e^{-R^2} + \pi$$

When  $R \rightarrow \infty$ ,  $e^{-R^2} \rightarrow 0$ ,

$$V = \int_0^\infty e^{-r^2} 2\pi r dr = \pi \quad (\text{same as in the darts problem})$$

Figure 9: Area of annulus or ring,  $(2\pi r)dr$ .

Next, we will find  $V$  by a second method, the method of slices. Slice the solid along a plane where  $y$  is fixed. (See Figure 10). Call  $A(y)$  the cross-sectional area. Since the thickness is  $dy$  (see Figure 11),

$$V = \int_{-\infty}^{\infty} A(y) dy$$

Figure 10: Slice  $A(y)$ .

Figure 11: Top view of  $A(y)$  slice.

To compute  $A(y)$ , note that it is an integral (with respect to  $dx$ )

$$A(y) = \int_{-\infty}^{\infty} e^{-r^2} dx = \int_{-\infty}^{\infty} e^{-x^2-y^2} dx = e^{-y^2} \int_{-\infty}^{\infty} e^{-x^2} dx = e^{-y^2} Q$$

Here, we have used  $r^2 = x^2 + y^2$  and

$$e^{-x^2-y^2} = e^{-x^2} e^{-y^2}$$

and the fact that  $y$  is a constant in the  $A(y)$  slice (see Figure 12). In other words,

$$\int_{-\infty}^{\infty} c e^{-x^2} dx = c \int_{-\infty}^{\infty} e^{-x^2} dx \quad \text{with} \quad c = e^{-y^2}$$

Figure 12: Side view of  $A(y)$  slice.

---

It follows that

$$V = \int_{-\infty}^{\infty} A(y) dy = \int_{-\infty}^{\infty} e^{-y^2} Q dy = Q \int_{-\infty}^{\infty} e^{-y^2} dy = Q^2$$

Indeed,

$$Q = \int_{-\infty}^{\infty} e^{-x^2} dx = \int_{-\infty}^{\infty} e^{-y^2} dy$$

because the name of the variable does not matter. To conclude the calculation read the equation backwards:

$$\pi = V = Q^2 \implies \boxed{Q = \sqrt{\pi}}$$

We can rewrite  $Q = \sqrt{\pi}$  as

$$\frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} e^{-x^2} dx = 1$$

An equivalent rescaled version of this formula (replacing  $x$  with  $x/\sqrt{2}\sigma$ ) is used:

$$\frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{\infty} e^{-x^2/2\sigma^2} dx = 1$$

This formula is central to probability and statistics. The probability distribution  $\frac{1}{\sqrt{2\pi}\sigma} e^{-x^2/2\sigma^2}$  on  $-\infty < x < \infty$  is known as the normal distribution, and  $\sigma > 0$  is its standard deviation.
